

Chapter 12-1

Inter-procedural Analysis

Data Flow Analysis (DFA)

- How do we define a DFA?

Data Flow Analysis (DFA)

- How do we define a DFA?
- What are flow-insensitive, flow-sensitive, and path-sensitive analysis?

Data Flow Analysis (DFA)

- How do we define a DFA?
- What are flow-insensitive, flow-sensitive, and path-sensitive analysis?
- What are symbolic execution and concolic execution?

Inter-procedural DFA

Inter-procedural DFA

- Why inter-procedural DFA?

Inter-procedural DFA

- Why inter-procedural DFA?
 - virtual method invocation

```
public void foo(List l, int x) { l.add(x); }
```

Inter-procedural DFA

- Why inter-procedural DFA?
 - virtual method invocation
 - detection of software defects
 - ...

```
public void foo(List l, int x) { l.add(x); }
```

Bug #87203, which is detected by our work

36 functions over 11 compiling units

PART I: Basics

Call Graph (CG)

A bit different from the definition in the dragon book.

- Nodes --- Functions
- Edges --- Call relations between functions
- Edge Labels --- Call sites

Call Graph (CG)

```
int (*pf)(int);

int fun1(int x) {
    if (x < 10)
c1:        return (*pf)(x+1);
    else
        return x;
}

int fun2(int y) {
    pf = &fun1;
c2:        return (*pf)(y);
}

void main() {
c3:        pf = &fun2; fun1(1);
c4:        fun2(5)
}
```

Call Graph (CG)

```

int (*pf)(int);

int fun1(int x) {
    if (x < 10)
        return (*pf)(x+1);
    else
        return x;
}

int fun2(int y) {
    pf = &fun1;
    return (*pf)(y);
}

void main() {
    c3:    pf = &fun2; fun1(1);
    c4:    fun2(5)
}
  
```

Call Graph (CG)

```

int (*pf)(int);

int fun1(int x) {
    if (x < 10)
        return (*pf)(x+1);
    else
        return x;
}

int fun2(int y) {
    pf = &fun1;
    return (*pf)(y);
}

void main() {
    c3:    pf = &fun2; fun1(1);
    c4:    fun2(5)
}
  
```

Call Graph (CG)

```

int (*pf)(int);

int fun1(int x) {
    if (x < 10)
        return (*pf)(x+1);
    else
        return x;
}

int fun2(int y) {
    pf = &fun1;
    return (*pf)(y);
}

void main() {
    pf = &fun2; fun1(1);
    fun2(5)
}
  
```

c1: return (*pf)(x+1);

c2: return (*pf)(y);

c3: pf = &fun2; fun1(1);

c4: fun2(5)

It may call different functions based on
different calling contexts
--- call chains (CG paths)!

Call Chains

```

int (*pf)(int);

int fun1(int x) {
    if (x < 10)
        return (*pf)(x+1);
    else
        return x;
}

int fun2(int y) {
    pf = &fun1;
    return (*pf)(y);
}

void main() {
    pf = &fun2; fun1(1);
    fun2(5)
}
  
```

c1: return (*pf)(x+1);

c2: return (*pf)(y);

c3: pf = &fun2; fun1(1);

c4: fun2(5)

It may call different functions based on
different calling contexts
--- call chains (CG paths)!

Call Chains

Call chains:

- $C_3-C_1-\dots$
- $C_4-C_2-C_1-\dots$
- ...

```

int (*pf)(int);

int fun1(int x) {
    if (x < 10)
        return (*pf)(x+1);
    else
        return x;
}

int fun2(int y) {
    pf = &fun1;
    return (*pf)(y);
}

void main() {
    pf = &fun2; fun1(1);
    fun2(5)
}
  
```

It may call different functions based on different calling contexts
--- call chains (CG paths)!

Call Chains

Call chains:

- $C_3-C_1-\dots$
- $C_4-C_2-C_1-\dots$
- ...

```

int (*pf)(int);

int fun1(int x) {
    if (x < 10)
c1:      return (*pf)(x+1);
    else
        return x;
}

int fun2(int y) {
    pf = &fun1;
c2:      return (*pf)(y);
}

void main() {
c3:      pf = &fun2; fun1(1);
c4:      fun2(5)
}
  
```

It may call different functions based on different calling contexts
--- call chains (CG paths)!

Call Chains

Call chains:

- $C_3-C_1-\dots$
- $C_4-C_2-C_1-\dots$
- ...

```

int (*pf)(int);

int fun1(int x) {
    if (x < 10)
c1:      return (*pf)(x+1);
    else
        return x;
}

int fun2(int y) {
    pf = &fun1;
c2:      return (*pf)(y);
}

void main() {
c3:      pf = &fun2; fun1(1);
c4:      fun2(5)
}
  
```

It may call different functions based on different calling contexts
--- call chains (CG paths)!

Context Sensitivity

Call chains:

- $C_3-C_1-\dots$
- $C_4-C_2-C_1-\dots$
- $\dots$

```

int (*pf)(int);

int fun1(int x) {
    if (x < 10)
        return (*pf)(x+1);
    else
        return x;
}

int fun2(int y) {
    pf = &fun1;
    return (*pf)(y);
}

void main() {
    c3:    pf = &fun2; fun1(1);
    c4:    fun2(5)
}
  
```

Context Sensitivity

Call chains:

- $C_3-C_1-\dots$
- $C_4-C_2-C_1-\dots$
- $\dots$

```

int (*pf)(int);

int fun1(int x) {
  if (x < 10)
    return (*pf)(x+1);
  else
    return x;
}

int fun2(int y) {
  pf = &fun1;
  return (*pf)(y);
}

void main() {
  pf = &fun2; fun1(1);
  fun2(5)
}
  
```

If an analysis can answer in what call chains, fun_1 calls fun_1 , we say the analysis is context-sensitive!

Context Sensitivity

Call chains:

- $C_3-C_1-\dots$
- $C_4-C_2-C_1-\dots$
- ...

```

int (*pf)(int);

int fun1(int x) {
    if (x < 10)
        return (*pf)(x+1);
    else
        return x;
}

int fun2(int y) {
    pf = &fun1;
    return (*pf)(y);
}

void main() {
    pf = &fun2; fun1(1);
    fun2(5)
}
  
```

c1: return (*pf)(x+1);

c2: return (*pf)(y);

c3: pf = &fun2; fun1(1);

c4: fun2(5)

An analysis is **context-insensitive**, it can only produce:
fun₁ may call fun₁ or fun₂

If an analysis can answer in what call chains, fun₁ calls fun₁, we say the analysis is context-sensitive!

Context Sensitivity

Call chains:

- $C_3-C_1-\dots$
- $C_4-C_2-C_1-\dots$
- ...

```

int (*pf)(int);

int fun1(int x) {
    if (x < 10)
        return (*pf)(x+1);
    else
        return x;
}

int fun2(int y) {
    pf = &fun1;
    return (*pf)(y);
}

void main() {
    pf = &fun2; fun1(1);
    fun2(5)
}
  
```

To distinguish different function behaviors at different contexts

Context Sensitivity

Call chains:

- $C_3-C_1-\dots$
- $C_4-C_2-C_1-\dots$
- ...

```

int (*pf)(int);

int fun1(int x) {
    if (x < 10)
        return (*pf)(x+1);
    else
        return x;
}

int fun2(int y) {
    pf = &fun1;
    return (*pf)(y);
}

void main() {
    pf = &fun2; fun1(1);
    fun2(5)
}
  
```

To distinguish different function behaviors at different contexts

Recap:

- Flow-sensitivity
- Path-sensitivity

Context-Sensitive DFA

- **Clone-based** interprocedural DFA
- **Summary-based** interprocedural DFA

Clone-Based Analysis

```
        for (i = 0; i < n; i++) {  
c1:          t1 = g(0);  
c2:          t2 = g(243);  
c3:          t3 = g(243);  
             X[i] = t1+t2+t3;  
        }  
  
    int g (int v) {  
c4:        return f(v);  
    }  
  
    int f (int v) {  
        return (v+1);  
    }
```

Clone-Based Analysis

```
        for (i = 0; i < n; i++) {  
c1:         t1 = g(0);  
c2:         t2 = g(243);  
c3:         t3 = g(243);  
            X[i] = t1+t2+t3;  
        }  
  
    int g (int v) {

ABSTRACT

Bottom-up program analysis has been traditionally easy to parallelize because functions without caller-callee relations can be analyzed independently. However, such function-level parallelism is significantly limited by the calling dependence - functions with caller-callee relations have to be analyzed sequentially because the analysis of a function depends on the analysis results, i.e., function summaries, of its callees. We observe that the calling dependence can be relaxed in many cases and, as a result, the parallelism can be improved. In this paper, we present *Coyote*, a framework of bottom-up data flow analysis, in which the analysis task of each function is elaborately partitioned into multiple sub-tasks to generate pipelineable function summaries. These sub-tasks are pipelined and run in parallel, even though the calling dependence exists. We formalize our idea under the IFDS/IDE framework and have implemented an application to checking null-reference bugs and taint issues in C++ programs. We evaluate *Coyote* on a series of standard benchmark programs and open-source software systems, which demonstrates significant speedup over a conventional parallel design.

1 INTRODUCTION

Bottom-up analyses work by processing the call graph of a program upwards from the leaves - before analyzing a function, all its callee functions are analyzed and summarized as function summaries [4, 8, 9, 11, 15, 16, 54, 63, 64]. These analyses have two key strengths: the

function summaries they compute are highly reusable and they are easy to parallelize because the analyses of functions are decoupled. While almost all existing bottom-up analyses take advantage of such function-level parallelization, there is little progress in improving its parallelism. As reported by recent studies, it still needs to take a few hours, even tens of hours, to precisely analyze large-scale software. For example, it takes 6 to 11 hours for Saturn [64] and Calysto [4] to analyze programs of 685KLoC [4]. It takes about 5 hours for Pinpoint [54] to analyze about 8 million lines of code. With regard to the performance issues, McPeak et al. [53] pointed out that the parallelism often drops off at runtime and, thus, the CPU resources are usually not well utilized. Specifically, this is because the parallelism is significantly limited by the *calling dependence* - functions with caller-callee relations have to be analyzed sequentially because the analysis of a caller function depends on the analysis results, i.e., function summaries, of its callee functions. To illustrate this phenomenon, let us consider the call graph in Figure 1 where the function f calls the functions, g and h . In a conventional bottom-up analysis, only functions without caller-callee relations, e.g., the function g and the function h , can be analyzed in parallel. The analysis of the function f cannot start until the analyses of the functions, g and h , complete. Otherwise, when analyzing a call site of the function, g or h , in the function f , we may miss some effects of the callees due to the incomplete analysis.¹

Figure 1: Conventional parallel design of bottom-up program analysis. Each rectangle represents the analysis task for a function.

Figure 2: The analysis task of each function is partitioned into multiple sub-tasks. All sub-tasks are pipelined.

¹This is different from a top-down method that can let the analysis of the function f run first but stop to wait for the analysis results of the functions g when analyzing a call statement calling the function g .

PART II: DFA as Graph Reachability

Recap: Constant Propagation

- Each variable $v \rightarrow \text{UNDEF, Constant, NAC}$, denoted as $m(v)$

Recap: Constant Propagation

- Each variable $v \rightarrow \text{UNDEF, Constant, NAC}$, denoted as $m(v)$

Indexing CFL Reachability

Indexing the Extended Dyck-CFL Reachability for Context-Sensitive Program Analysis

QINGKAI SHI, Ant Group, China
YONGCHAO WANG, The Hong Kong University of Science and Technology, China
PEISEN YAO, The Hong Kong University of Science and Technology, China
CHARLES ZHANG, The Hong Kong University of Science and Technology, China

Many context-sensitive dataflow analyses can be formulated as an extended Dyck-CFL reachability problem, where function calls and returns are modeled as partially matched parentheses. Unfortunately, despite many works on the standard Dyck-CFL reachability problem, solving the extended version is still of quadratic space complexity and nearly cubic time complexity, significantly limiting the scalability of program analyses. This paper, for the first time to the best of our knowledge, presents a cheap approach to transforming the extended Dyck-CFL reachability problem to conventional graph reachability, a much easier and well-studied problem. This transformation allows us to benefit from recent advances in reachability indexing schemes, making it possible to answer any reachability query in a context-sensitive dataflow analysis within almost constant time plus only a few extra spaces. We have implemented our approach in two common context-sensitive dataflow analyses, one determines pointer alias relations and the other tracks information flows. Experimental results demonstrate that, compared to their original analyses, we can achieve orders of magnitude ($10^2\times$ to $10^5\times$) speedup at the cost of only a moderate space overhead. Our implementation is publicly available.

CCS Concepts: • Mathematics of computing → Graph algorithms; • Theory of computation → Program analysis; • Software and its engineering → Automated static analysis.

Additional Key Words and Phrases: Dyck-CFL reachability, context sensitivity, reachability indexing scheme.

1 INTRODUCTION

The problem of context-free language (CFL) reachability is a generalization of the problem of conventional graph reachability [Yannakakis 1990]. A vertex v is CFL-reachable from a vertex u if and only if there is a path from the vertex u to the vertex v , and the string of the edge labels follows a given context-free grammar. CFL reachability has been broadly used in program analysis for a wide range of applications, including context-sensitive dataflow analysis [Reps et al. 1995], program slicing [Reps et al. 1994], shape analysis [Reps 1995], type-based flow analysis [Kodumal and Aiken 2004; Milanova 2020; Pratikakis et al. 2006; Rehof and Fähndrich 2001], pointer analysis [Pratikakis et al. 2006; Shang et al. 2012; Sridharan et al. 2005; Xu et al. 2009; Yan et al. 2011; Zhang et al. 2013, 2014; Zheng and Rugina 2008], and debugging [Cai et al. 2018], to name just a few.

CS-DDA across Different Levels

- Answer any diff-level data dependence query in $\sim O(1)$ after $\sim O(n)$ preprocessing
- **Key Idea:**
 - (1) Use same-level CS-DDA to build summary edges
 - (2) Transform diff-level CS-DDA to conventional reachability
 - (3) Apply reachability indexing techniques

CS-DDA across Different Levels

```

void bar() {
(1)   int b = foo();
(2)   int d = baz(b);
(3)   qux(d);
}

void qux(int e) {
(4)   fax(e);
}

int foo() {
      int g = ...; a = ...;
(5)   baz(g);
      return a;
}

int baz(int c) { return c; }
(6) void fax(int f) { qux(f); }
    
```

CS-DDA across Different Levels

Many context-sensitive dataflow analyses can be formulated as an extended Dyck-CFL reachability problem, where function calls and returns are modeled as partially matched parentheses. Unfortunately, despite many works on the standard Dyck-CFL reachability problem, solving the extended version is still of quadratic space complexity and nearly cubic time complexity, significantly limiting the scalability of program analyses. This paper, for the first time to the best of our knowledge, presents a cheap approach to transforming the extended Dyck-CFL reachability problem to conventional graph reachability, a much easier and well-studied problem. This transformation allows us to benefit from recent advances in reachability indexing schemes, making it possible to answer any reachability query in a context-sensitive dataflow analysis within almost constant time plus only a few extra spaces. We have implemented our approach in two common context-sensitive dataflow analyses, one determines pointer alias relations and the other tracks information flows. Experimental results demonstrate that, compared to their original analyses, we can achieve orders of magnitude ($10^2 \times$ to $10^3 \times$) speedup at the cost of only a moderate space overhead. Our implementation is publicly available.

CCS Concepts: • Mathematics of computing → Graph algorithms; • Theory of computation → Program analysis; • Software and its engineering → Automated static analysis.

Additional Key Words and Phrases: Dyck-CFL reachability, context sensitivity, reachability indexing scheme.

1 INTRODUCTION

The problem of context-free-language (CFL) reachability is a generalization of the problem of conventional graph reachability [Yannakakis 1990]. A vertex v is CFL-reachable from a vertex u if and only if there is a path from the vertex u to the vertex v , and the string of the edge labels follows a given context-free grammar. CFL reachability has been broadly used in program analysis for a wide range of applications, including context-sensitive dataflow analysis [Reps et al. 1995], program slicing [Reps et al. 1994], shape analysis [Reps 1995], type-based flow analysis [Kodumal and Aiken 2004; Milanova 2020; Pratikakis et al. 2006; Rehof and Fähndrich 2001], pointer analysis [Pratikakis et al. 2006; Shang et al. 2012; Sridharan et al. 2005; Xu et al. 2009; Yan et al. 2011; Zhang et al. 2013, 2014; Zheng and Rugina 2008], and debugging [Cai et al. 2018], to name just a few.
